A Health Disparity Study among Undergraduate Students and Graduate Students at a HBCU

Aim: Our study consisted of surveying undergraduate and graduate students at an HBCU about their knowledge of certain health disparities that affect African Americans.

Ethical Approval: Approval from the Allen University Institutional Review Board was granted to administer an online anonymous health disparity questionnaire to undergraduate and graduate students at Allen University. The questionnaire was administered using the community based participatory research (CBPR) methodology.

Sampling Criteria and Size of Participants: The sampling criteria consisted of undergraduates enrolled in the Biological Sciences course, Biology I course, Biology II course, or Freshman Seminar course during the spring 2020 semester. The sampling also consisted of graduate students that were currently enrolled in the Dickerson-Green Seminary. The sample size consisted of 114 participants that completed the online questionnaire. Data Analysis: The data from the metabolic syndrome questionnaire was analyzed using descriptive statistics, utilizing percentages from a cross-tabulation of individual responses. Results: Most of the participants were African American (96.5%), female (54.9%) and between the ages of 18 and 21 (60.5%). Between 73% and 90.4% of the participants knew that each disease on the survey disproportionately affected African Americans. However, less than 50% knew the risk factors of breast cancer, risk factors of cervical cancer, risk factors of prostate cancer, symptoms of prostate cancer, symptoms of sickle cell anemia and treatments for sickle cell anemia. Conclusion: The next phase of our study will consist of conducting a metabolic syndrome (MetS) questionnaire with the graduate students. The data, along with data from the MetS questionnaire conducted with the undergraduates in a previous study, and the health disparity questionnaire data will be used to construct health disparity educational workshops at Allen.

Keywords: Health disparities, historically black colleges and universities, African American college students

Introduction

There are several health disparities associated with African Americans. Some of the health disparities are asthma, breast cancer, cervical cancer, prostate cancer, and sickle cell anemia (U.S. Department of Health and Human Services, 2020).

According to the National Health Interview Survey, African Americans had a 10.7% prevalence of having asthma (Center for Disease Control, 2018). This is in comparison to Asians (4.5%), Mexicans (5.4%), Hispanics (6.5%), and Caucasians (8%). The data also indicated that African American adults had a 9.6% prevalence of having asthma. This data is significant when compared to Asians (3.8%), Mexicans (6.6%), Caucasians (6.8%), and Hispanics (7.5%).

Between 2013 and 2017, the rate of new cases of breast cancer was 128.5 per 100,000 women (National Cancer Institute, 2020). The data also indicated that African American women had the second highest rate of breast cancer, which was 124.8 per 100,000 women, outside of the rate of 131.3 per 100,000 in Caucasian women. This is in comparison to the rates among Asian/Pacific Islander women (102.9), Hispanic women (99.1), and American Indian/Alaska Native women (79.5). The data indicated that the death rate among African American women
from breast cancer was 27.6 per 100,000 women as well. This rate was
significantly higher than the death rate among Asian/Pacific Islander women
(11.4), Hispanic women (14.0), American Indian/Alaska Native women (14.6),
and Caucasian women (19.8). It is estimated that approximately 276,480 new
cases of breast cancer and approximately 42,120 deaths from breast cancer will
occur in 2020 in women (National Cancer Institute, 2020).

Hispanic women had the highest rate of new cases of cervical cancer between
2013 and 2017, which was 9.2 per 100,000 (National Cancer Institute, 2020).
However, African American women had the second highest rate of new cases of
cervical cancer which was 8.7 per 100,000 women. The rate was higher than
Asian/Pacific Islander women (6.5), Caucasian women (7.2), and American
Indian/Alaska Native women (7.9). Also, the data indicated that the death rate
from cervical cancer in African American women was 3.4 per 100,000 women.
This was significantly higher than the death rate in Asian/ Pacific Islander women
(1.8), Caucasian (2.2), American Indian/Alaska Native women (2.5), and Hispanic
women (2.6). It is estimated that 13,800 new cases of cervical cancer and an
estimated 4,290 deaths from cervical cancer will occur in 2020 (National Cancer
Institute, 2020).

Unfortunately, African American men had the highest rate of new cases of
prostate cancer between 2013 and 2017, with a rate of 175.3 per 100,000 men
(National Cancer Institute, 2020). This was in comparison to American
Indian/Alaska Native (54.6), Asian/Pacific Islander men (56.7), Hispanic men
(92.0), and Caucasian men (102.3). The death rate among African American men
from prostate cancer was 37.9 per 100,000 men, which was indicated in the data as
well. The death rate was drastically high in comparison to Asian/Pacific Islander
men (8.6), Hispanic men (15.8), Caucasian men (17.9), and American
Indian/Alaska Native men (18.7). An estimated 191,930 new cases of prostate
cancer and an estimated 33,330 deaths from prostate cancer is predicted to occur in
2020 (National Cancer Institute, 2020).

The Centers for Disease Control (CDC) estimates that sickle cell anemia
affects approximately 100,000 Americans (Centers for Disease Control, 2020).
Also, the CDC estimates sickle cell anemia occurs in 1 out of 365 African
American births. In addition, 1 in 13 African American babies are estimated by
the CDC to be born with the sickle cell anemia trait (SCT).

Given the statistical information regarding the prevalence of asthma, breast
cancer, cervical cancer, prostate cancer, and sickle cell anemia among African
Americans, it is imperative to investigate the knowledge of these health issues
among African American college students. Our research study was constructed to
survey undergraduate students and graduate students at Allen University, an
HBCU with a large population of African American students, about their
knowledge of these health disparities. Overall, the results will provide the basis for
developing an educational program to help reduce and prevent these health
disparities among the undergraduate and graduate student population at Allen.
Methods

Ethical Approval

An anonymous online questionnaire on health disparities associated with African Americans was reviewed and approved by the Allen University Institutional Review Board. The questionnaire template in Google Forms was used to create the online questionnaire. The questionnaire consisted of a total of 42 questions. The first few questions on the online form consisted of the following: ethical background, age, gender, classification, major, family health history, and individual health. The questions that followed assessed the participant’s knowledge regarding asthma, breast cancer, cervical cancer, prostate cancer and sickle cell anemia.

Sampling Criteria and Size of Participants

The undergraduate students that were recruited to complete the health disparity questionnaire were primarily freshman and African American. The graduate students that were recruited for the study were primarily African American. The community based participatory research (CBPR) methodology (Wallerstein and Duran, 2006) was used to conduct the online questionnaire among the undergraduate students and graduate students. The undergraduate participants that participated in the study were enrolled in the Biological Sciences course, Biology I course, Biology II course, or Freshman Seminar course at Allen. The graduate participants were enrolled in the Dickerson-Green Theological Seminary at Allen. The students were invited to participate in completing the questionnaire which was administered in the spring of 2020 during their class time. The undergraduate courses were chosen because they consist of large class sizes in comparison to the upper level courses. All of the students were informed that their participation in the questionnaire was voluntary and that a written consent was required before they could complete the questionnaire. All participants were also informed that they could withdraw from completing the questionnaire at any time without any adverse consequences. Each undergraduate student that completed the questionnaire received extra credit points. The graduate students that completed the questionnaire did not receive any extra credit points. The consent form that was completed by the participants was maintained in a designated locked facility. A total of 114 participants completed the questionnaire.

Data Analysis

The data obtained from the online health disparities questionnaire was reviewed from the responses recorded on the Google Forms survey. The questionnaire was analyzed using descriptive statistics, utilizing percentages from a cross-tabulation of individual responses.
Results

The demographics of the participants consisted of 96.5% African American, 3.5% Caucasian, 2.7% Native American, 1.8% Asian, 0.9% African, 0.9% Jamaican, and 0.9% Hispanic. Also, 55.7% were freshman, 8.0% were sophomores, 1.8% were juniors, 1.8% were seniors and 32.7% were graduate students. A total of 54.9% of the participants were female and 45.1% were male.

The age of the participants consisted of 60.5% that were between 18-21 years, 4.4% between 22-25 years, 1.8% between 26-29 years, 2.6% between 30-39 years, 5.3% between 40-49 years, 11.4% between 50-59 years, and 14% between 60 years and older. A total of 33.3% of the students were obtaining a Master of Divinity degree, followed by an undergraduate degree in biology (18.4%), undergraduate degree in sports management (12.3%) and undergraduate degree in business (11.4%).

There were 43.4% of participants that were athletes in comparison to 57.5% that were not athletes. In regards to a healthy lifestyle, the data indicated that 36% of the participants exercised 3 to 4 times a week, 25.4% exercised once a week, 18.4% exercised 2-3 times a week, 7.9% exercised once a month and 14% didn’t exercise. In addition, the data indicated that 4.4% of the participants were current tobacco smokers, 6.1% were former tobacco smokers and 91.2% were non-tobacco smokers. Moreover, 30.7% of the participants ate healthy, 69.3% sometimes ate healthy, and 2.6% didn’t eat healthy.

Figure 1. Family History of Diseases of the Undergraduate Participants and Graduate Participants that completed the Online Health Disparity Questionnaire

The data from the online questionnaire indicated that the graduate students had a significantly lower percentage of not having a family history of asthma, breast cancer, cervical cancer, and sickle cell anemia. The percentage for the
graduate participants that didn’t have a family history of the diseases listed above was 13%, in comparison to 28.7% among the undergraduate students. The data indicated also that there was a significantly lower percentage of a family history of asthma among the graduate participants (9.3%), in comparison to the undergraduate participants (30.5%). There was a slight difference between the number of graduate participants (0.9%) with a family history of sickle cell anemia in comparison to the undergraduate participants (3.7%). Interestingly, the graduate students and undergraduate students had the same percentage (3.7%) for a family history of cervical cancer. On the other hand, the percentages for a family history of breast cancer among the graduate students (11.1%) and undergraduate students (13%) was not significantly different. However, the data from the questionnaire did indicate that the graduate students had a slightly higher rate of prostate cancer (8.3%) in their family than the undergraduate students (5.6%).

Figure 2. Individual Health History of Diseases of the Undergraduate Participants and Graduate Participants

The data for the individual health history indicated that the 0.9% of a personal health history of prostate cancer was solely based on the data from the graduate students. The undergraduate participants didn’t indicate that they had a personal history of prostate cancer. The individual health history for breast cancer indicated that the graduate students didn’t have a significant higher percentage of breast cancer (2.8%) than the undergraduate students (1.9%). The percentage of graduate students and undergraduate students that had sickle cell anemia was the same, which was 0.93%. However, the percentage of graduate students (5.6%) that had asthma was significantly lower than the percentage for the undergraduate students (17.79%). The percentage of graduate students (27.1%) that did not have any of the health issues listed was significantly lower than the undergraduate students (45.8%) as well.

Overall, the undergraduate participants and graduate participants did know that each disease on the survey disproportionately affected African Americans. The percentage of participants that indicated that information on the questionnaire for each disease was the following: 90.4% (asthma), 77.7% (breast cancer), 73% (cervical cancer), 75% (prostate cancer), and 81.3% (sickle cell anemia).

*The answers to this question on the questionnaire consisted of more than one answer. However, the participants only chose one answer. The top answer that was chosen is indicated by the percentages listed for the overall, undergraduate participants and graduate participants.

The majority of the participants (59.1%) chose an inhaling and exhaling test for the diagnosis of asthma. However, the correct answer was spirometry test and peak flow test. Only 15.5% of the participants, 5.5% undergraduate students and 10% of the graduate students, chose the correct answer.

The majority of the participants (48.2%) only chose a family history of breast cancer as the answer for the risk factors associated with breast cancer. A total of 32.5% of the participants only chose an inherited gene (mutation BRCA1 and
BRCA2) as the answer. However, all of the answers listed on the questionnaire were risk factors for breast cancer. The answer for the question regarding the risk factors for cervical cancer was all of the answers listed. However, the majority of the participants (40.4%) only chose the answer that pertained to having been diagnosed with other sexually transmitted infections. Also, the majority of the participants (66.7%) only chose surgery as a treatment for cervical cancer rather than all of the treatments listed. In addition, the question pertaining to the symptoms of cervical cancer resulted in 34.2%, 32.5%, and 33.3% of the participants only choosing the first, second or third answer, respectively. All three answers that were listed were the symptoms. For the question regarding cervical cancer screening, both of the answers listed on the questionnaire were the correct answers. However, 66.1% of the participants only chose a Pap smear test and 33.9% only chose an HPV DNA test. The answer regarding the risk factors associated with prostate cancer consisted of all of the answers listed on the questionnaire. However, 43.2% of the participants only chose age as a risk factor for prostate cancer and 41.4% of the participants only chose a family history of prostate cancer. Also, the majority of the participants (41.8%) only chose problems urinating as the answer to the symptoms associated with prostate cancer instead of all of the answers listed. For the question regarding the symptoms for sickle cell anemia, all of the answers that were listed were the risk factors. However, the majority of the participants (43.9%) only chose the following answer: low iron count, fatigue, frequent infections and episodes of pain. Also, the majority of the participants only chose one of the treatments listed for sickle cell anemia instead of all of the answers listed. Most of them (43.9%) chose blood transfusions as the treatment for sickle cell anemia.

Discussion

The number of participants that completed the questionnaire for our health disparity study was a total of 114. The majority of the participants were African American (96.5%), female (54.9%), and between the ages of 18 to 21 (60.5%). Also, the majority of the participants were freshman (55.7%) and 43.4% of the participants were athletes. A total of 32.7% of the participants were graduate students. A mere 1% of the participants didn’t indicate their gender, age, classification or if they were an athlete. Also, 2% of the participants didn’t indicate their ethnic background. In addition, 5.3% of the participants didn’t indicate if they had a family history of the diseases listed on the survey. A total of 6.2% of the participants didn’t indicate if they had any of the diseases listed on the survey as well. Even though this data wasn’t obtained from those participants, the percentages were not significant. There was a higher percentage of a family history of asthma, sickle cell anemia, or no family history of the health issues listed among the undergraduate participants (67.3%) in comparison to the graduate students (32.7%). The high
percentages were due to the fact there were more undergraduate students that completed the online questionnaire than graduate students. This also contributed to a higher percentage of undergraduate students that had asthma or indicated that they didn’t have any of the health issues listed.

The results of our study also indicated that the participants had general knowledge pertaining to asthma. A total of 78.1% of the participants, 45.6% undergraduate students and 32.5% graduate students, knew the symptoms of asthma. The results also indicated that 77.2% of the participants, 48.2% undergraduate students and 29.0% graduate students, knew the treatments for asthma. More than likely, this general knowledge was the result of the number of participants that had asthma (23.4%) or had a family history of asthma (39.8%). Some of the results of our study can be compared to a cross-sectional study that explored asthma knowledge and beliefs among African American adults in a Midwestern city (Tam-Williams et al., 2018). The study surveyed 158 African American adults. Among the participants, 38.3% of them had been diagnosed with asthma, 78% had family members with asthma, and 59.8% that has cared for someone with asthma. The results of their study indicated that the participants had a good general knowledge of asthma.

There was no significant difference in the percentage of graduate participants that had a personal history of breast cancer than the undergraduate participants. There were 3 female graduate students that had a personal history of breast cancer. The participants were 60 years or older and African American. The 2 undergraduate participants that had a personal history of breast cancer were between the ages of 18 to 21. Both students were African American, but one undergraduate student was male, and the other undergraduate student was female.

There was, however, a lack of knowledge of the risk factors for breast cancer for all participants. The majority of the participants only chose a family history of breast cancer instead of all of the risk factors listed. The results of our study can be compared to three other breast cancer studies that involved college students that were black. One study was conducted at Winston-Salem University among the campus community and the city/county community (Powell et. al., 2008). The majority of the participants were African American (99%) and educated (31% college students; 42% college graduate and less; 14% advanced degrees and education). The study indicated that the mean score of knowledge about breast cancer was 23.25. A breast cancer study was conducted several years later in Raleigh, Durham, and Chapel Hill, North Carolina that consisted of six focus groups of African American women between the ages of 18 and 49 years (Allicok et. al., 2013). A total of 33% of the participants had some college education and 53% of the participants had a college degree. The participants had little knowledge of breast cancer and thought that a family history of breast cancer could predispose a person to the disease. Sub-Saharan countries unfortunately have a high mortality rate of breast cancer in African women. This led to a study that was conducted among college students in Angola, which is a Sub-Saharan African country. In the study, the data indicated that there was a widespread lack of knowledge of the risk factors associated with breast cancer. In addition, the most known risk factor for breast cancer among the participants was a family history of breast cancer.
In Ethiopia, the incidence of breast cancer has increased. The increase influenced some researchers to conduct a questionnaire study on breast cancer among college students at the University of Gondar in Northwest Ethiopia. Their study indicated that the overall level of knowledge on breast cancer was low. Also, 75% of the participants indicated that a family history of breast cancer was a risk factor of breast cancer (Gebresillassie et. al., 2018).

All of the participants in our study only chose one risk factor for cervical cancer instead of all of the answers listed. They also only chose one treatment for cervical cancer instead of all of the answers that were listed. The results of our study can be compared to other studies that were conducted among university students in America, South Africa and Ghana. One of the cervical cancer studies was conducted with African American women at a HBCU in the mid-Atlantic region of the United States that were between the age of 18 and 21 (Bowen-Reid et. al., 2017). The results of their study indicated that the individual item analysis suggested that there were deficits in basic knowledge about cervical cancer (etiology of HPV, transmission of HPV, screening strategies and prevention strategies) among the participants. Unfortunately, cervical cancer is the second common cancer in South Africa. Thus, a cervical cancer study was conducted among university students in South Africa. The study indicated that the women that participated in the study lacked complete knowledge of cervical cancer and its risk factors (Hoque et. al., 2018). Sadly, the leading cause of mortality among women in Ghana is cervical cancer. Based on this information, researchers conducted a cross-sectional cervical cancer study among college women in a university in Ghana. The study indicated that there was a lack of knowledge by the students regarding a link between smoking and cervical cancer (Abotchie and Shokar, 2009). In our study, only 7.9% of the participants indicated that smoking tobacco products is a risk factor for cervical cancer.

The percentage of a personal history of prostate cancer among the participants in our study was low, which was at a mere 0.9%. The percentage was derived from one subject that was an African American male and a graduate student. A higher percentage of the participants (13.9%) had a family history of prostate cancer which consisted of 8.3% of the graduate students and 5.6% of the undergraduate students. In regards to the risk factors for prostate cancer, our data indicated that 43.2% of the participants selected age for their answer, which consisted of 36% undergraduate and 7.2% graduate students. Two prostate cancer studies can be compared to our study. One study occurred at a HBCU in the southern United States and was conducted among 35 African American men that ranged in age between 18 and 34 years (Mincey et. al., 2017). The participants of the study included freshmen (24%), sophomores (27%), juniors (15%), seniors (27%), and graduate students (9%). Approximately 15% of the participants of their study had a family history of prostate cancer, which was 1.1% higher than the percentage in our study. Also, their study reported that their participants felt they were at a greater risk for prostate cancer because of their ethnic background. In our study, 75% of the participants knew that prostate cancer disproportionately affects African Americans. Another study was conducted among men in Austin, Texas (Ogunsanya et. al., 2017). The majority of the participants were in college...
(68.2%), graduate school (11.4%), or had a second degree (23.5%). A total of 95.9% of the participants in their study were black (African American, African or Caribbean). Overall, the knowledge of the participants in the study regarding prostate cancer was low, especially the knowledge related to risk factors. The mean correct responses of the participants consisted of 28.5%. The mean knowledge score was 5.25% ± 3.81, with a median score of 5.00.

The percentage of graduate students and undergraduate students with a personal health history of sickle cell anemia was the same. The data could possibly be associated with the fact that 1 out of 365 African American are estimated to have sickle cell anemia (CDC, 2020). Also, the undergraduate and graduate participants only chose 1 risk factor for sickle cell anemia. Most of them (43.9%) chose the following: low iron count, fatigue, frequent infections, and episodes of pain. The participants chose only 1 treatment for the treatment of sickle cell anemia as well. The majority of them (43.8%) chose blood transfusions as the treatment for sickle cell anemia. Two other sickle cell anemia studies can be compared to our study. One study was conducted at a North Texas campus with college students that consisted of freshman, sophomores, juniors, seniors and graduate students. Of the 15.6% of the African American students that participated in the study, 66.2% of the them were knowledgeable about sickle cell anemia in comparison to 69.2% of the Caucasian students (Smith and Praetorius, 2018). A non-experimental, cross sectional sickle cell anemia research study was conducted at the University of Texas at Arlington. A total of 415 college students participated that consisted of 15.7% African Americans, 16.9% Hispanics, 19.8% Asians, and 37.9% Caucasians. The study indicated that the males and the minority participants had less knowledge about sickle cell disease than the Caucasian participants (Smith and Brownell, 2018).

Questions regarding diabetes and obesity, which are health disparities that also greatly effect African Americans, were not included on the questionnaire. This was due to the fact that data had been obtained from the undergraduate students in a previous study regarding diabetes and obesity. The results of study indicated that 41% of the undergraduate students had a family history of diabetes. In the study, 60.8% of the undergraduate students knew how diabetes is defined and 54.1% of them were able to identify the types of diabetes. Also, a total of 33.8% of the undergraduate students knew how obesity was defined and 17.6% knew the risk factors for obesity. The study, however, didn’t include the graduate students at Allen since the focus for the study was the knowledge of the undergraduate students regarding the risk factors of metabolic syndrome.

The questionnaire didn’t include questions regarding high cholesterol, heart diseases or stroke, which are health disparities that effect African Americans as well. The questions were not included on the questionnaire since a previous study had been conducted with undergraduate students regarding those health disparities. The study indicated that 13.5% of the undergraduate students had a family history of high cholesterol, 15% had a family history of a heart attack, and 13.5% had a family history of a stroke. Also, 31% of the participants knew how high cholesterol is detected and 23% knew how high blood pressure is measured. More than half of the participants were able to identify the risk factors for high blood
pressure and 48% knew how a heart attack occurs. In addition, 20.9% knew the symptoms of a heart attack, 35.1% knew when a stroke occurred, and only 25.7% knew about the symptoms of a stroke. This study did not include the graduate students at Allen since the focus for the study was the knowledge of these health disparities by the undergraduate students.

Conclusion

Analysis of the data from our health disparity study indicates that it is imperative to improve the knowledge that our undergraduate and graduate students have about the risk factors of breast cancer, cervical cancer, and prostate cancer. The data also indicates that the knowledge of the undergraduates and graduates regarding the treatments for cervical cancer and symptoms of prostate cancer needs to improve. Additionally, the knowledge of the symptoms and treatments for sickle cell anemia need to increase among the undergraduate and graduate students.

Even though asthma, breast cancer, cervical cancer, prostate cancer and sickle cell anemia disproportionately affect African Americans, there is a significant lack of studies by Historically Black Colleges and Universities regarding the knowledge of African American college students about these health disparities. To our knowledge, asthma studies involving questionnaires and college students at HBCU’s haven’t been published. Only a few survey studies have been published that are related to breast cancer, cervical cancer and prostate cancer among African American college students at an HBCU. A few breast cancer survey studies and cervical cancer survey studies have been conducted with college students attending a university in Africa. These studies are significant because of the high rate of breast cancer and cervical cancer rates among African women, just as it is with African American women. Also, more sickle cell anemia studies need to be conducted at HBCUs. Some sickle cell anemia survey studies have been conducted with college students in the United States, but the percentage of African American participants is extremely low in both studies which is 15.6% and 15.7%, respectively.

An educational intervention cervical cancer study was conducted among college students at Hampton University, North Carolina Central University, West Virginia State University and Marshall University. The study indicated that the knowledge about cervical cancer among the 57 participants that completed the pre- and post-intervention surveys increased significantly. The study was able to successfully improve the knowledge of the participants about HPV and cervical cancer (Staples et. al., 2018). Thus, if more research regarding asthma, breast cancer, cervical cancer, prostate cancer and sickle cell anemia is conducted with African American college students at HBCU’s then intervention programs could be established to educate them about these health disparities as a preventative measure.

The next phase of our study is to administer an online metabolic syndrome questionnaire to the graduate students to determine their knowledge of obesity,
diabetes, heart disease and stroke. The data will also be compared to the data obtained from the undergraduates from a previous MetS study. Based on the data from the MetS questionnaires and the health disparity questionnaire, we plan to develop health disparity educational workshops. The educational workshops will be used to educate the undergraduate students and graduate students about health disparities that are associated with African Americans. The educational workshops will serve as preventative measures in the attempt to reduce the number of undergraduate students and graduate students from developing breast cancer, cervical cancer, prostate cancer, high blood pressure, high cholesterol, diabetes or becoming obese. The educational workshops will also help the undergraduate students and graduate students that have asthma, high blood pressure, high cholesterol, diabetes or sickle cell anemia to manage the health issue.
