

1 **Estimating the Economic Benefits of Biotechnology in** 2 **Canada's Canola**

3
4 *Canola refers to varieties of rapeseed that have been explicitly bred for human*
5 *and livestock consumption when processed into meal and oil. Canola has become*
6 *a dominant cultivar in Canada due, in part, to the introduction of modern*
7 *biotechnology, and the industry has experienced substantial growth. The paper*
8 *provides a current overview and assessment of the importance of biotech canola*
9 *to the Canadian economy. It also examines the economic benefits of new*
10 *biotechnology at the farm level, including a recent estimation of the producers'*
11 *benefits. We estimate that producers' benefits were just under \$2 billion in the*
12 *2023/24 crop year. Lastly, the implications of the results for research policy are*
13 *discussed.*

14
15 **Keywords:** *Biotechnology, Canola, R&D, Economic Benefits, Producers' Benefits*

16 17 18 **Introduction**

19
20 Canola is a type of oilseed rape bred at Canada's federal research station in
21 Saskatoon and at the University of Manitoba in Winnipeg, Manitoba, in the early
22 1970s (Canola Council of Canada, 2024a, 2024b). The researchers had worked to
23 reduce the levels of some of rapeseed's non-food oils and acids. Canola was
24 developed to ensure that new varieties of the seed and, in turn, the resulting oil and
25 meal products were deemed safe for human and animal consumption. The first
26 registered variety with low levels of both erucic acid and glucosinolates, or "double
27 low", rapeseed cultivars. The success of Canola as a crop has been a fascinating
28 story of public and private biotechnological innovation.

29 The agricultural sector worldwide faces significant challenges amid
30 constrained research budgets, increasing pressures from population growth, and
31 shifting consumption patterns and dietary preferences. It has been demonstrated that
32 agricultural productivity growth has slowed, particularly in the world's wealthiest
33 countries. Alston, Beddow, and Pardey (2010a) attributed the global productivity
34 slowdown to underinvestment in certain types of productivity-enhancing
35 agricultural research and development (R&D). Canada's canola crop may appear
36 more productive in terms of higher commodity prices and improved varieties;
37 however, by all reasonable estimates, there is still underinvestment in agricultural
38 research.

39 There is substantial evidence that investment in biotechnology, where some
40 property rights have been assigned, can contribute to growth and benefit farmers,
41 consumers, the environment, and the economy as a whole (e.g., EASAC, 2013;
42 United Nations, 2017; FAO, 2022). However, optimal policies and regulations
43 designed to foster investment must adapt as societal needs change, as does the
44 market structure and the crops that dominate a landscape. The policies and
45 regulations in place must be assessed to ensure further growth in the sector.

46 Governments in Canada and around the world have historically played a
47 significant role in agricultural research (e.g., Malla and Gray, 2003, 2005; Malla and

1 Brewin, 2019a). During the 20th century, most crop research was conducted by
2 public institutions, and the resulting products were held in the public domain. At
3 the root of support for public agricultural research was the notion that the innovator
4 could not capture all the benefits of research, as benefits “spilled over” to adopters.
5 The introduction of modern biotechnology and strengthened Intellectual Property
6 Rights (IPRs) has conferred monopolistic rights on innovators, stimulating
7 increased private investment in agricultural research. These changes were
8 particularly apparent in the Canadian canola sector, which has undergone significant
9 alterations over the last three decades. The large influx of private investment in
10 Canadian canola has led some to conclude that there is no longer a role for public
11 investment in crop research. Others have raised concerns about potential adverse
12 effects of privatizing agricultural research, such as reduced “freedom to operate” for
13 some breeding firms. The canola sector has experienced fragmented research and
14 patent/IPR ownership, as well as mergers and acquisitions, and, more recently, a
15 growing need for gene-trait cross-licensing agreements. Gene trait cross-licensing
16 agreements have raised concerns about economies of scale in biotechnology and the
17 close relationships new agreements necessitate between the few dominant firms
18 remaining in the sector. Furthermore, there have been concerns that the
19 commercialization of a second generation of biotech products could suffer from the
20 underuse of resources and less innovation (the tragedy of the anti-commons). There
21 have also been concerns about the pricing of new canola varieties, the rules
22 governing the use of new technology, potential crowding out of private investment,
23 and the appropriate role for government in today’s biotech industry.

24 In contrast to the case of canola, wheat and pulse research has mainly been
25 publicly funded in Canada (e.g., Malla and Brewin 2019a). Wheat represents the
26 other major crop in Canada around the same area as canola, while pulse crops
27 represent a smaller cluster of crops. However, the area devoted to pulse crops has
28 significantly increased since the 1980s, and Canada has become a leading producer,
29 exporter, and research leader for pulses worldwide. A large portion of pulse research
30 is producer-funded through the mandatory Saskatchewan Pulse Growers (SPG)
31 check-off. The question that arises is whether today’s government involvement in
32 canola and other crop research is suitable, sufficient, and adequate. Comparing
33 experiences across different locations and crops can provide valuable quantitative
34 and qualitative insights into the effects of privatization and innovation policies.

35 The goal of this study is to develop a broader understanding of how agricultural
36 crop research, related regulations, policies, and key industry trends have evolved in
37 the Canadian canola industry, and to consider how these changes impact farm
38 returns and what that means for future public innovation policy. Specifically, the
39 objectives of this paper are to provide a current assessment of biotechnology's
40 importance, examine its economic benefits, estimate the benefits to producers, and
41 explore policy implications.

42
43
44

1 **An Overview of the Importance of Canola in Canada**

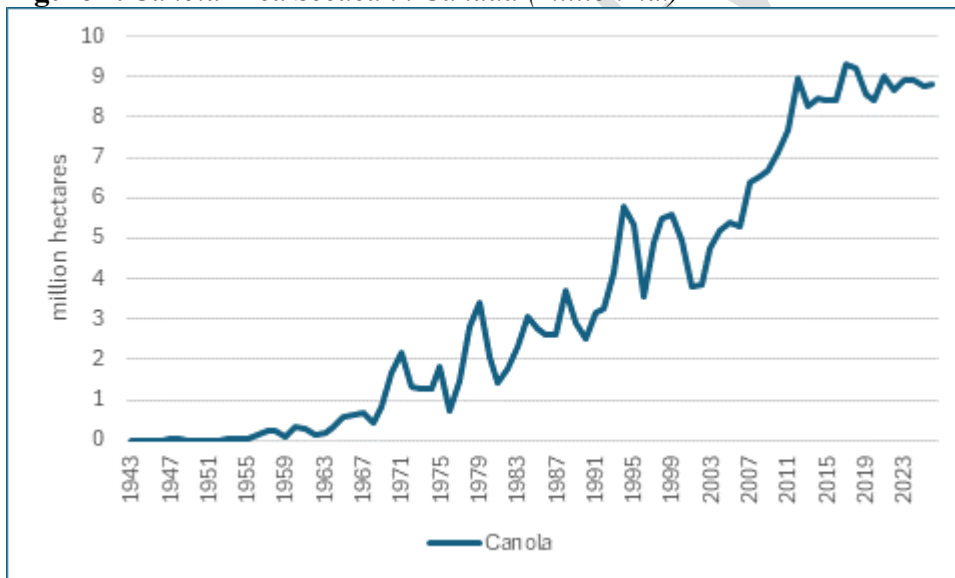

2

3 A canola sector overview starts with the story of canola’s rise in Canada from
 4 a very minor crop used to make industrial oil to the largest generator of farm income
 5 in Canada as of 2024. Figure 1 illustrates the evolution of the seeded area over time,
 6 reaching a current level of over 8 million hectares. Canola is seeded on around one-
 7 third of all arable land in Canada – another third is seeded to wheat, and a third for
 8 a range of other crops, including corn, soybeans, barley, lentils, and peas (Statistics
 9 Canada, 2026).

10 The gain in area was not due to prices, at least not until recent peaks. Wheat
 11 was the dominant crop in Canada from its colonization until about 2010. The prices
 12 for wheat, canola, and all oilseeds and cereals have generally moved together
 13 because worldwide cereals and oilseeds are planted on the same ground – prices
 14 adjust as buyers bid for acres in the spring. This typically keeps the returns to cereals
 15 and oilseeds in balance. Figure 2 shows Canadian wheat and canola prices as an
 16 index of the 2012 price from 1997 to 2012. It is clear that the two crop prices have
 17 moved fairly close together until the end of the series.

3
4
5 Canola played a significant role in changing the use of summer fallow in
6 Canada and offered a valuable addition to crop rotations centred on wheat and barley
7 for most of Canada. Figure 3 shows the reductions in wheat and summer fallow
8 areas as the canola area increased. These rotational choices were part of the growing
9 canola area in the 1970s and 1980s and represent a major shift in soil health;
10 however, this paper will focus on the yield and herbicide impacts of biotechnology
11 in canola, particularly the rise of Herbicide-Tolerant (HT) seed varieties since 1996.
12

16
17

1 Table 1 lists the 20 most successful varieties of canola seed in Canada over
2 time. The crop's area increased with the development of the Echo seed in 1965. Still,
3 it improved with the introduction of Tobin, a Polish variety with a shorter growing
4 season that performed well in Canada's northern prairies (Brewin and Malla, 2015).
5 The area experienced another surge in 1984, when Westar was developed. All three
6 of these varieties were developed at Agriculture Canada Research Stations (Brewing
7 and Malla, 2015). Although some Herbicide Tolerant (HT) varieties were developed
8 using patented traits in 1996, it was the InVigor technology of the early 2000s that
9 helped ramp up the area seeded to canola in Canada, and two varieties (5440 and
10 L150) are now among the top four in area ever seeded to a variety (Brewin and
11 Malla, 2015). The InVigor technology continues to lead in terms of the areas seeded
12 in 2025 (Yield Manitoba, 2025). InVigor utilizes glufosinate (Liberty) HT in
13 competition with glyphosate (Roundup) HT varieties, and as InVigor was explored,
14 Bayer also identified male sterility, which facilitated less costly hybridization for
15 canola. This path to hybridization enabled significant gains in hybrid vigour in
16 canola varieties, especially with Bayer, which held the patent in Canada for
17 LibertyLink HT until a recent merger between Monsanto and Bayer led to the sale
18 of the InVigor Canola patents to BASF. After 2003, all of the most popular canola
19 seed varieties were both HT and hybrid. Because hybrid seeds suffer a significant
20 yield drop in the second generation, farmers are willing to pay for new hybrid seed
21 every year, which helps drive private investment, along with the HT patents, which
22 also drive seed investment.¹ Together, the increased yields and reduced herbicide
23 costs facilitated effective weed control within our wheat and canola rotations.
24
25

¹ The tradition of farmers saving seed in the wheat market and early canola varieties led to farmers pushing back on the fees charged by Monsanto for seed containing the first patented traits. The Case of Percy Schmeizer versus Monsanto ended up in Canada's Supreme Court and is told in the 2020 movie "Percy" starring Christopher Walken.

1 **Table 1.** *Top 20 Canola Seed Varieties by Seeded Area 1969 to 2012*

6 **The Direct Benefits of Biotech Canola for Producers**

7
8 In the mid-1990s, when the first HT fees were being collected, the seed
9 companies charged more for the technology than the average farmer was willing to
10 pay. Fulton and Keyowski (1999) demonstrated that the average Saskatchewan
11 farmer would incur a loss by adopting any of the available HT Varieties in 1996.
12 There was likely strong demand for farmers with weed problems, such that the
13 herbicide gains and improved yields from reduced weed competition had a better
14 payback than the average farm. As time progressed, competition among seed
15 growers and technological advancements began to alter the calculus within seed
16 firms, and farmers started earning significantly more from adopting HT hybrids than
17 from sticking with cheaper, publicly bred, open-pollinated varieties.

18 In 2015, Malla and Brewin estimated the total direct benefits to farmers in
19 Canada for the 2011/12 crop year from biotech innovations in canola. They
20 estimated that gain to be over one billion Canadian dollars a year, using the data in
21 Table 2 and summing the last line. These gains are based on reduced herbicide costs
22 and higher yields that swamp higher seed costs when any one of three HT seed
23 systems was used. Roundup Ready (RR) varieties enabled farmers to spray
24 Roundup on their canola crops to control weeds. Liberty Link (LL) and Clearfield
25 allowed the application of two other herbicides. By 2012, 93% of the seeds used by
26 farmers in Canada were either RR or LL, and most were also produced with hybrid

1 strains. The yields in Table 1 were based on the 2011 crop, with an average yield of
 2 1.9 t/ha. As of 2023, the yield had improved to 2.17 tonnes per hectare, and prices
 3 had increased to \$ 715 per tonne (AAFC, 2025). The area seeded also increased
 4 from 8 million ha in 2011 to 8.86 million ha in 2023 (AAFC, 2025).

5
 6 **Table 2.** *Gains To Canola Farmers by the Seed System Adopted Relative to Open*
 7 *Pollinated (2011/12)*

Farmer System Costs	Roundup Ready	Liberty Link	Clearfield	Open Pollinated

13
 14 Source: Authors' update of Malla and Brewin (2015)

15

1 Table 3 presents an updated version of Table 2, incorporating the 2023 yield
2 and area in Canada, as well as the 2023/24 average price (AAFC, 2025). With
3 higher yields, near-record-high prices, and increased area, the value of the direct
4 impacts of biotech changes to canola on Canadian farmers was just under \$2 billion
5 in the 2023/24 crop year. At the time of writing, the price has returned to its previous
6 level, having traded above \$610/t for most of the last three years (AAFC, 2025).

9 **Benefits to Other Firms and Indirect Impacts**

11 GlobalData (2024) estimated the direct economic contribution of canola
12 farmers and the seed companies that supply these new seed systems to be \$13
13 billion. The value of canola to the rest of the canola value chain, including exporters,
14 crushers, oil bottlers, and meal feeders, as well as the benefits to end users, was
15 estimated to generate an additional \$5.7 billion in direct economic impact.

16 In 2019, Malla and Brewin (2019b) presented a theory related to socially
17 optimal research and development expenditures related to crop innovation. In the
18 presence of low public investment and significant positive externalities from a
19 trading crop, it can lead to substantial underinvestment in terms of the public good.
20 Most researchers who have examined Canadian public investment in crops have
21 suggested that we are underinvesting (e.g., Gray et al., 2001; Malla and Gray, 2003,
22 2005; Malla et al., 2004; Alston et al., 2010b; Gray, 2014). Underinvestment in the
23 canola sector has improved, with a path towards Intellectual Property Rights (IPR)
24 in herbicide-tolerant and hybrid seed systems; however, it remains lower than
25 expected, given the significant returns to firms that discover the next great canola
26 seed. However, even if research efforts were optimal to meet the needs of the current
27 sector in terms of private returns, there could be underinvestment if canola
28 production generates environmental and health-related public goods for Canadians.

29 There have been several meta-analyses, which are analyses of other studies,
30 that link canola oil consumption to reduced cholesterol levels (e.g., Ghobadi et al.,
31 2018; Amiri et al., 2020; Pourrajab et al., 2022; Shen et.al. (2023). Shen et.al.
32 (2023) concluded that “Apart from unsaturated fatty acids, there are nine functional
33 components in rapeseed oil that contribute to its anti-microbial, anti-inflammatory,
34 anti-obesity, anti-diabetic, anti-cancer, neuroprotective, and cardioprotective,
35 among others. These nine functional components are vitamin E, flavonoids,
36 squalene, carotenoids, glucoraphanin, indole-3-Carbinol, sterols, phospholipids,
37 and ferulic acid, which themselves or their derivatives have health-benefiting
38 properties.” Therefore, canola or rapeseed oil has a wide range of health-promoting
39 effects, including those related to cardiovascular disease (CHD), obesity, cancer,
40 diabetes, and others.

41 There have also been several studies linking canola production, genetically
42 modified crops, and biotechnology to environmental benefits such as climate
43 change mitigation, greenhouse gas emissions reduction, increased carbon
44 sequestration, reduced soil and water contamination, reduction in herbicide
45 application, chemical use and toxicity (e.g., Biden et al. 2018, Kovak, et.al., 2022;
46 Brookes, 2022; Smyth, et.al., 2024). For example, Brookes (2022) considered the

1 environmental impacts of genetically modified crops and estimated that the
2 greenhouse gas emission savings (including fuel-related savings and soil carbon
3 storage) are equivalent to 23.6 billion kg in global agriculture. Kovak et al. (2022)
4 calculated that the greenhouse gas emission savings (from fuel-related savings and
5 soil carbon storage) are equivalent to 33 million tons of CO₂ equivalents per year in
6 the EU. This is comparable to the opportunity costs of delaying the adoption of GM
7 crops in North America. Biden et al. (2018) estimated that carbon emission savings
8 (fuel use only) amount to 24.2 million kilograms in Australia, or the opportunity
9 costs of delaying the adoption of GM canola, as seen in Canada (2004-2014).

12 **Concluding Comments**

14 Canola has become a major crop in Canada primarily due to the introduction of
15 modern biotechnology. The paper provides a current assessment of the economic
16 consequences of new biotechnology. Specifically, it examined the importance of
17 biotechnology and the economic benefits it brings, and estimated the benefits to
18 producers.

19 It has been demonstrated that significant benefits are associated with the new
20 biotech canola varieties, including increased area seeded to canola, expanded variety
21 options, reduced herbicide costs, and higher yields. There have also been substantial
22 benefits to producers and other firms, as well as the indirect benefits of biotech
23 canola development in Canada. The study estimated that the value of the direct
24 impacts of biotech changes to canola on Canadian producers was just under \$2
25 billion for the 2023/24 crop year. Overall, the economic benefits of biotechnology
26 are very substantial.

27 However, the high rate of returns on canola research investment suggests
28 underinvestment in research. Hence, more research investment is needed, and the
29 government's role is still vital in today's biotech canola industry. Government
30 policies that can stimulate more private R&D investment in the biotech canola
31 industry, such as government subsidies on the cost of private R&D investment or
32 research output, and the public provision of basic research, are essential.
33 Additionally, increased public R&D investment in applied research is also crucial.
34 Appropriate policies and programs could contribute to further growth of the canola
35 sector, increase overall economic benefits, and increase social well-being.
